FOREWORD

THIS present volume is intended to supplement our well-known collection of building details, entitled "Radford's Portfolio of Details of Building Construction," which was first issued in 1912 and has since run thru many editions.

All of the plates in the present series are new—not duplicating at all the earlier work. They present many of the modern ideas, that have come to the front during the past ten years.

This collection of details is offered with the expectation and hope that it will be of great practical utility to carpenters, builders, mill men, lumber dealers, draftsmen and architects. The aim has been to make it a complete manual of modern building practice, all points being made clear and understandable by means of the working drawing—the language of the blue print and the universal language of the building trades.

This book is a collection of plates, accurately drawn by skilled draftsmen, showing clearly the details of modern building construction and finish. Brief explanatory text accompanies each plate, calling attention to some of the points illustrated. The drawings themselves, however, are of first importance and should be carefully studied. More helpful ideas and exact information are contained in a single one of these plates of details than could be crowded into a whole chapter of ordinary descriptive text.

Details are given showing the framing and construction of residences of every type—frame houses, brick houses, brick veneer houses, stucco houses, etc. Also every popular and attractive style of interior trim is fully detailed. Special ideas are presented for the appropriate interior finish for every room or part of the house. These ideas are worked out complete, the drawings showing both the arrangement of the room and all the interior trim, including built-in features, fully detailed.

This is the day of "built-in" space and labor-saving features in the home. Carpenters and builders are called on continually to plan and build buffets and sideboards for the dining room; kitchen cabinets, cases, and cupboards for the kitchen and pantry; wardrobes and linen closets for the chambers; and window seats, fireplaces with decorative mantels, and built-in bookcases for the living room and library. These drawings have been prepared to show exactly how this kind of work is done. Many practical ideas are embodied in them; and new and attractive designs are presented from which the carpenter, the architect, or the builder can draw for all or any of these.

Many valuable details are also included in this collection of special interest to the country carpenter and builder. These include barn framing details of all kinds, ice-house and cold storage construction, silo building, etc.

The practical utility of detail plates of this kind will probably be best appreciated by those who draw plans or who are called upon to make their own designs for building work. The drawings in this collection have been prepared to meet especially the needs of such workmen.

Especial attention is called to the Index. This has been made very complete, all the various features detailed on any of the plates being listed and cross-indexed so that they may be very quickly found, without the necessity of searching thru the entire work. Since all the plates are completely indexed for ready reference their full value is available for use by the busy man.

Logical Methods in Architectural Drafting

A KNOWLEDGE of architectural drafting is vitally essential to the carpenter, builder or contractor, who would develop both himself and his business to the greatest possible extent.

The builder who is able to work out a neat and accurate set of drawings or "plans" fully dimensioned and detailed, leaving nothing to chance, has a very decided advantage over his brother, who, without fully conceived ideas and plans, starts building, and trusts to luck and good fortune that everything will work out all right. Even rough sketch drawing with approximate dimensions are better than none, but only full and detailed sets of plans are advisable.

In evolving a set of working plans the first logical step is the sketch. The purpose of the sketch is to fix the various ideas of either the builder or his client or of both and to give some definite basis for a start.

The medium for the sketch may be either pencil, pen and ink, water color or wash, the first named being the most common and the simplest to use.

The value of the sketch to the "builder architect" can hardly be over-estimated, because if well and attractively done, it may bring valuable contracts, which might not be obtained if this means of expression were not used.

Preliminary or "thumb nail" sketches, as they are sometimes called, should not be over 3 or 4 inches in size. They are not drawn to any definite scale and their chief purpose is to show arrangement. They should, however, be kept in proportion as much as possible.

The type of plan for such a sketch must of course be determined upon before the first drawing is made and the deciding factors are, first, the character of the site, and, second, the style of the exterior.

If we analyze any number of house plans we will find that they may be broadly classified into two general types, namely, the central entrance or central hall type, and the side entrance or side hall type. In the first named, as illustrated (Fig. 1), we have a symmetrical arrangement of rooms opening from a central hallway. This is the typical "Colonial" plan and calls, as a rule, for that style of elevation. In Fig. 2 we have the second type shown; note that in this type we have a plan that is unsymmetrical and is adapted especially to the narrow city lot.

We will take as an illustration of the logical steps to follow in making a sketch the first type, or central hall plan. First determine the approximate proportion of the floor plan, says two as to three. 1. Sketch center line. 2. Draw front and rear outside wall lines representing the width of the wall by a single line. 3. Side wall lines. 4. Locate main partition lines. 5. Minor partition lines. 6. Rough in approximate position of openings, doors and windows.

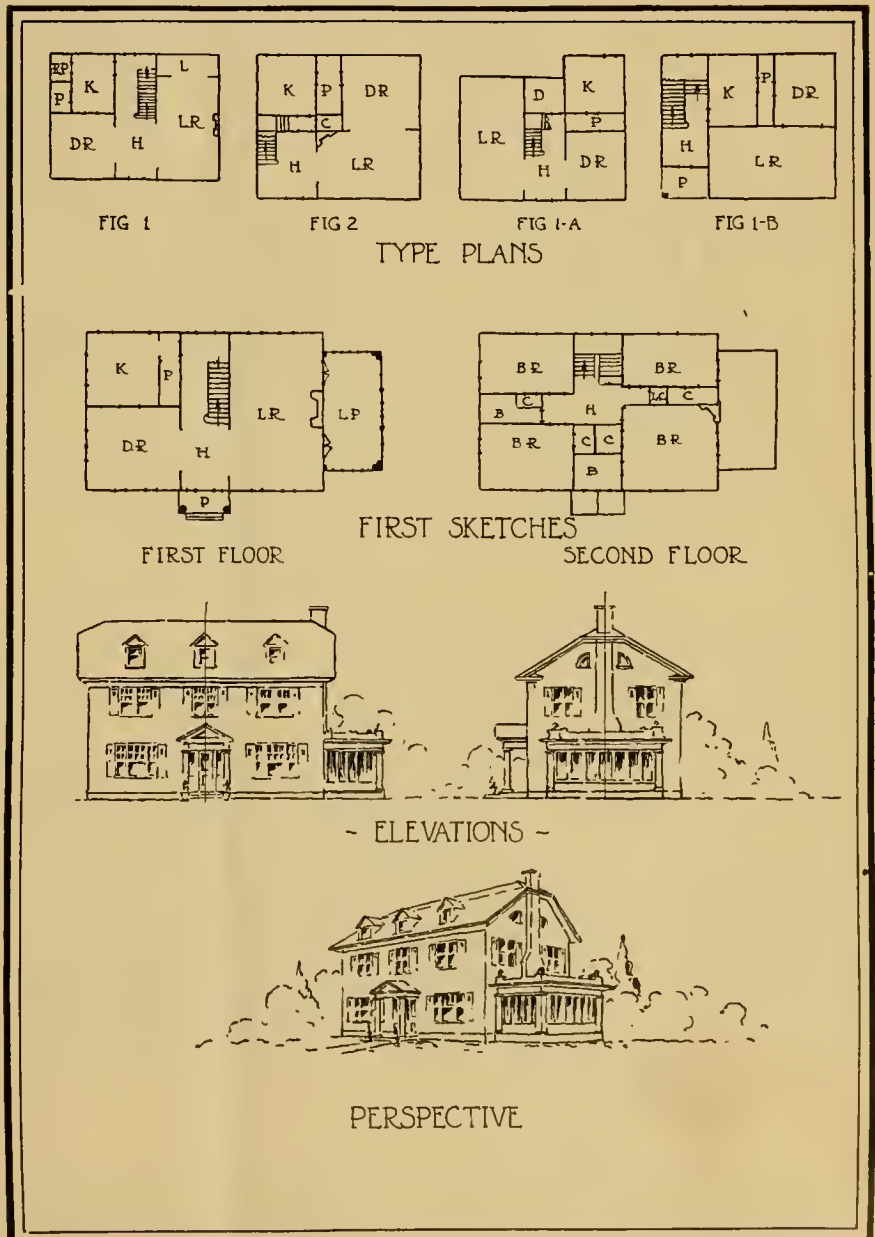

Study carefully at this time the relation of rooms and the circulation.

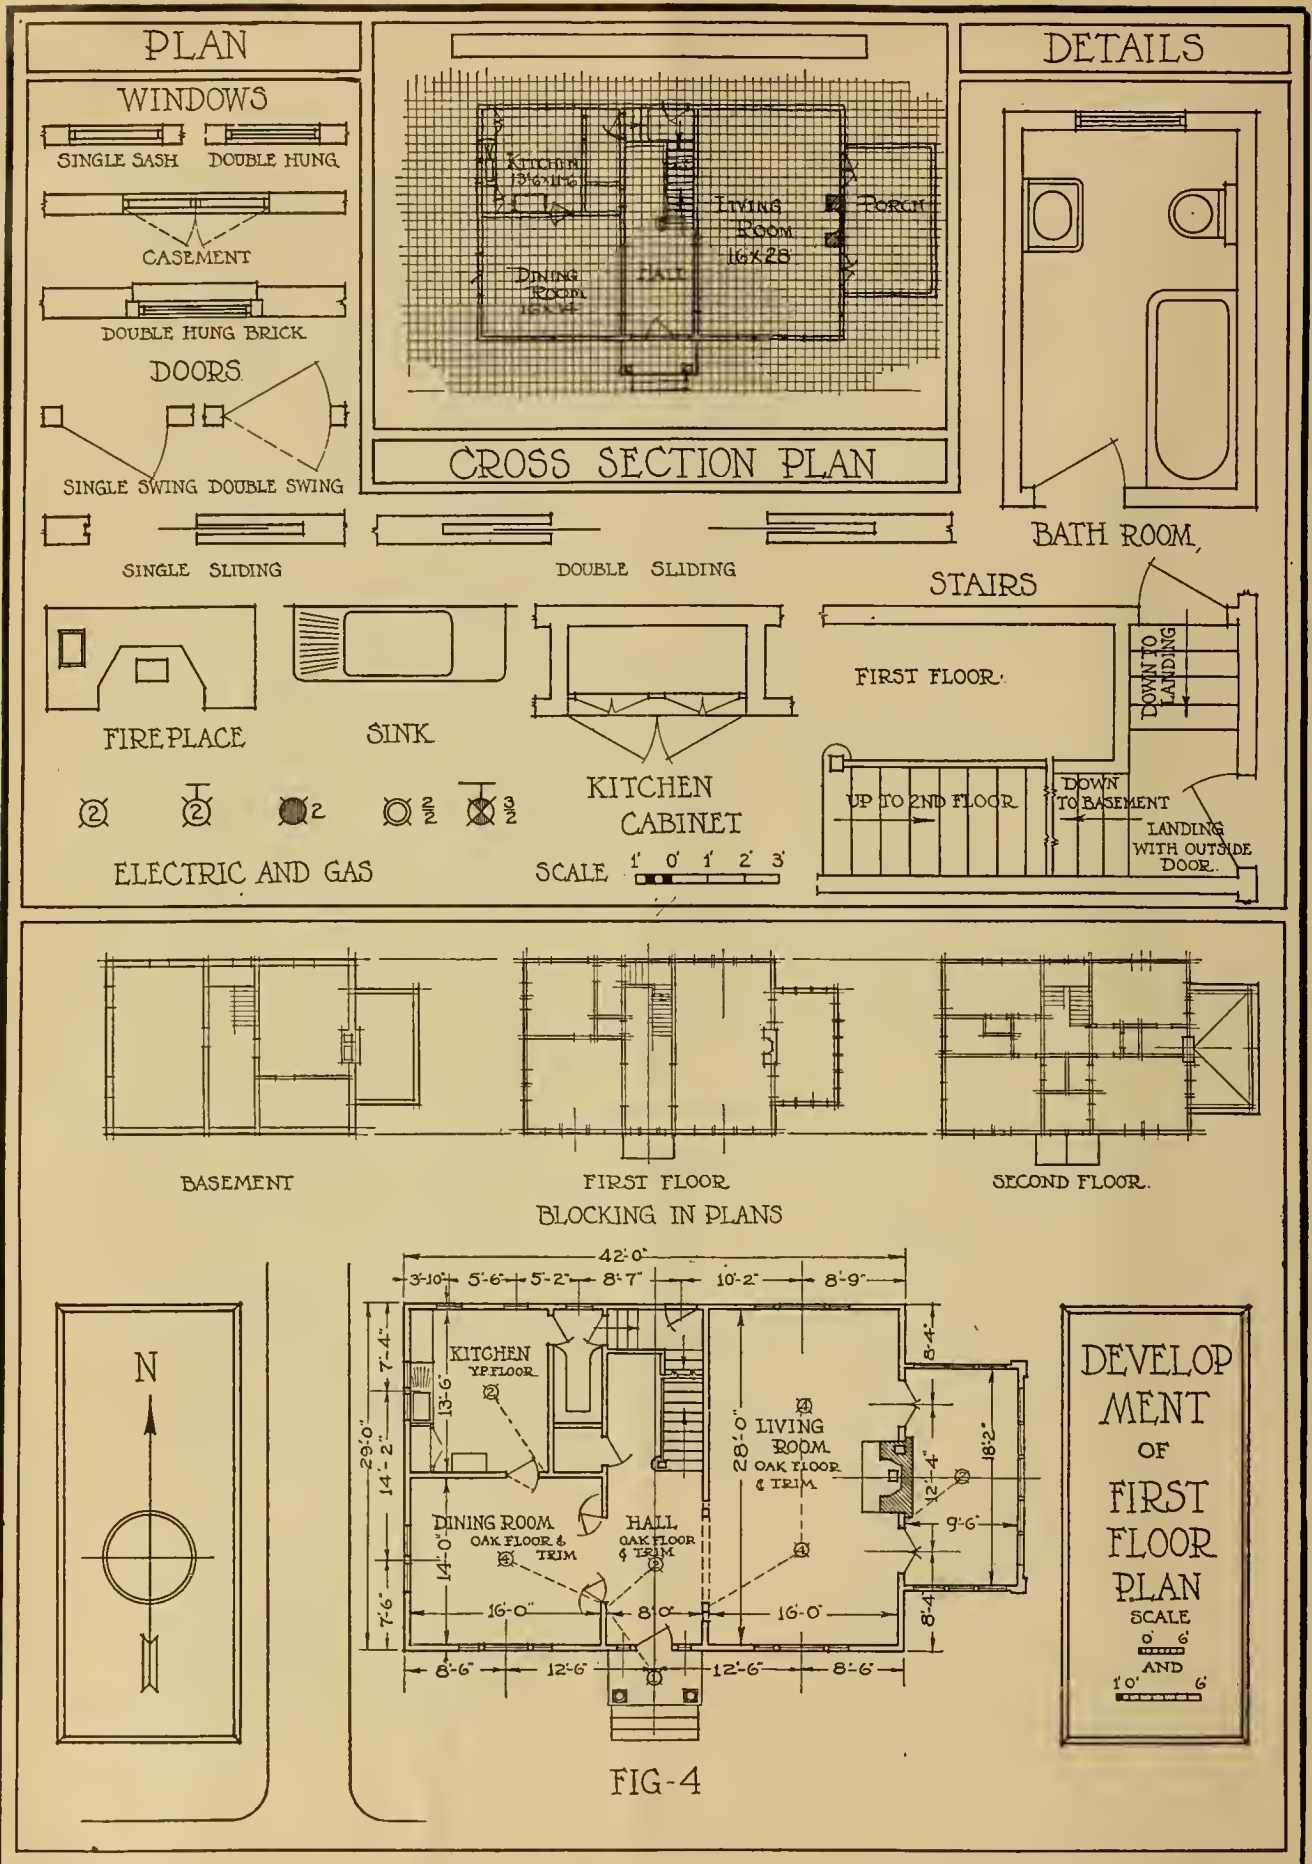

In like manner sketch second floor plan. It will be found that the basement, as a rule, logically takes its arrangement from the first floor plan, so we need not consider it in the first sketch.

After line sketches of the plans are made, the front elevation and then principal side elevation should be drawn.

The style of the exterior having been decided, determine first the proportion of the front wall—that is, the height from the ground to the under side of the cornice compared with the width. This height in the ordinary two-story house varies from 20 to 24 feet.

1. Block in this rectangle with center line.
2. Block in height lines for windows and doors.
3. Draw vertical outside lines for windows and doors, determining their positions approximately from plans.
4. Draw roof, taking height as $\frac{1}{4}$, $\frac{1}{3}$ or $\frac{1}{2}$ depth of plan, depending on judgment of designer.
5. Draw in porch or porches according to style of exterior.
6. Darken or shade window openings and show shadow under cornice.
7. Sketch in background.

Illustrating Logical Method of Developing the Floor Plans of a Residence.

DETAILS OF FIRE RETARDING CONSTRUCTION

DETAILS OF FIRE RETARDING CONSTRUCTION

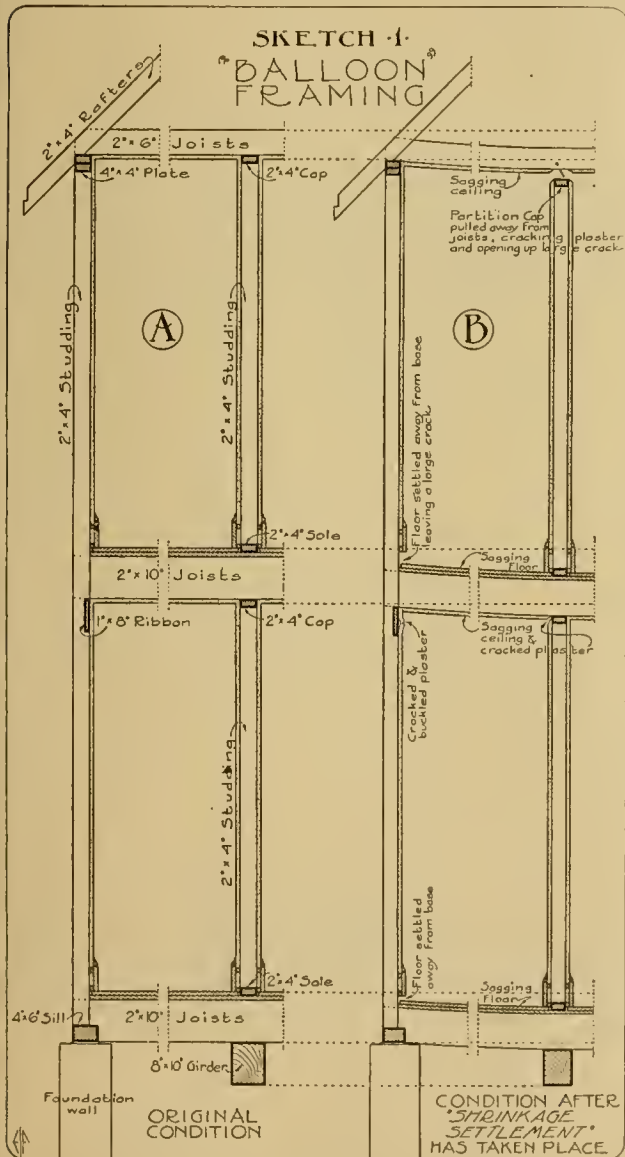

Framing to Prevent Unequal Shrinkage-Settlement

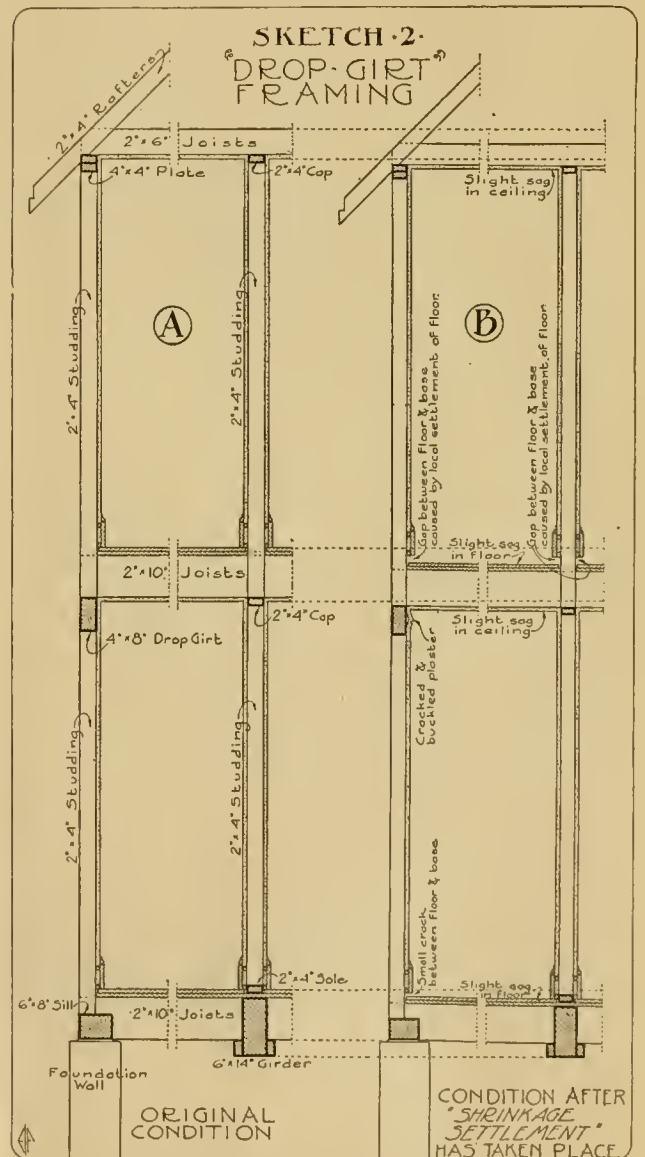

SKETCH No. 1 shows a cross-section of a "balloon" frame taken from an actual example. It is a glaring violation of all the principles of good construction, fire-resistance and sanitation. It's a fire trap, a vermin harbor, and is subject to a disastrous amount of *unequal settlement*. At "A" is shown the original condition of the framework just after being built. At "B" is indicated, graphically, the dilapidated and deplorable condition of affairs, a year later, after the inevitable shrinkage-settlement has taken place. And it is to be especially noted that the faults shown are not the result of settlement itself, but rather the result of the *difference* in settlement of corresponding and adjacent parts. If an engineer were to design a foundation in such a manner as to be productive of the faults shown, he would, most assuredly, be considered an exceedingly poor engineer. And rightly so. Why, then, in the name of common justice, is not the builder who, day after day, continues to design and frame the timber superstructure in the manner shown, deserving of the same amount of condemnation as the discreditable engineer? Wherein is the difference between an incompetent designer of foundations and an incompetent

designer of timber framing? As a matter of fact, the latter, in this particular case, is more to be censured than the former, for, in residence construction, seven cases out of ten the evils resulting from unequal settlement can be traced to the timber framework rather than to the foundation.

In the "balloon" framing, shown in Sketch No. 1, the exterior studding extends in one length from sill to rafter plate. Hence, the amount of shrinkable timber contributing to the total vertical settlement of the exterior wall is made up of the 4-inch sill and the 4-inch rafter-plate, equaling 8 inches in all. In like manner, the shrinkable bearing-timber in the interior partition is made up of the 10-inch girder, the two sets of 10-inch floor-joists, the two layers of 1-inch sub-flooring, the two 2-inch partition-soles, and the two 2-inch partitioning caps, totaling 40 inches. Hence, assuming an ultimate shrinkage of $\frac{1}{2}$ inch to the foot, the exterior wall will settle $\frac{1}{24}$ th of 8 inches, or only $\frac{1}{3}$ inch, while the interior partition will settle $\frac{1}{24}$ th of 40 inches, or $1\frac{2}{3}$ inches. And the *difference* of $1\frac{2}{3}$ inches is bound to cause trouble—floors sag, door frames are thrown out of square, plastering cracks, and the upper partition sometimes

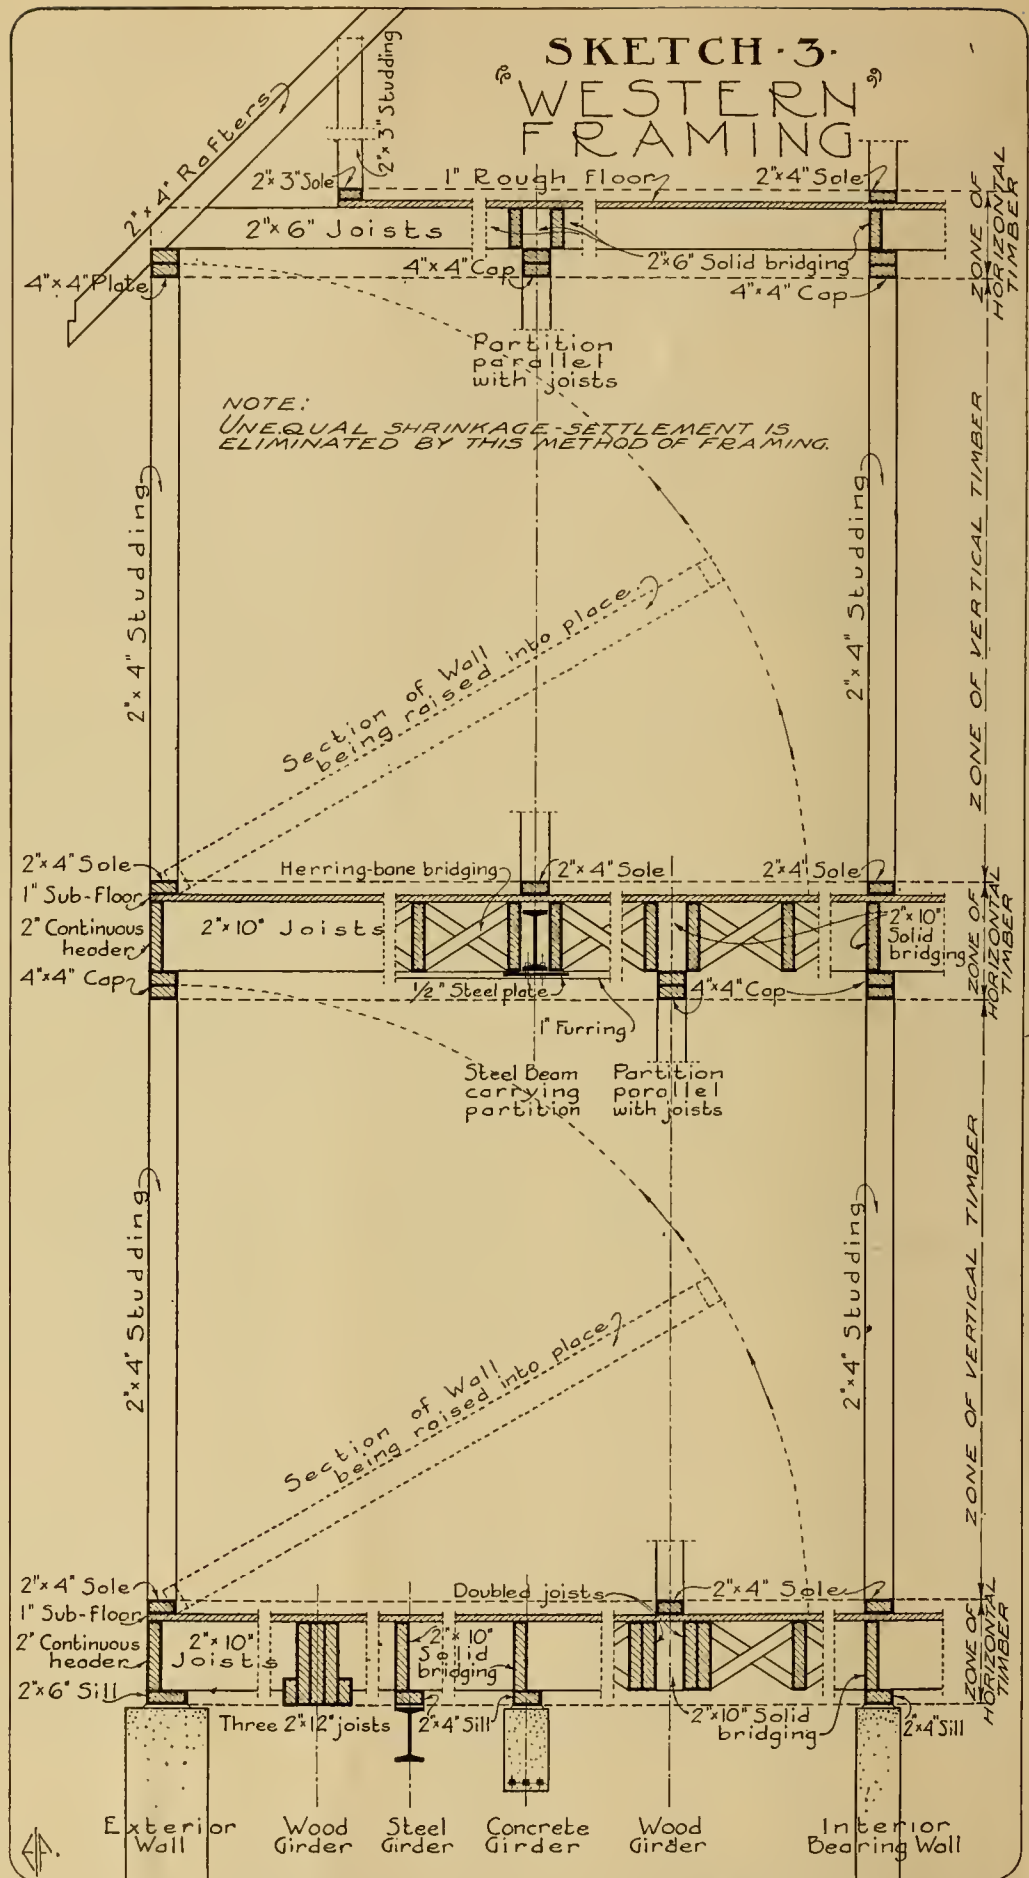

Showing Settlement Which Is Customary with Balloon Framing.

Showing Shrinkage Settlement with Drop-Girt Framing.

parts company with the ceiling overhead, or, perhaps, pulls away from the floor and hangs suspended from the ceiling-joints. Trouble enough, surely! But that is not all. Damaging local settlement also takes place at the outer ends of the floor joists, often leaving a wide gap between the finish floor and base-board, as shown exaggerated in the sketch. At the second floor line the total shrinkage of the 1-inch sub-floor, the 10-inch joists, and the 8-inch ribbon will measure the magnitude of the gap, equaling, in this case, about $\frac{3}{4}$ inch, for this shrinkage will always be *downward*, in the direction of the load, while no compensating relative settlement will take place in the vertical studding which extends thru this "zone" of horizontal bearing-timber. The base does not move in relation to the studding. But the floor *does*. Hence, the gap. At the interior partitions, however, the vertical studding does not extend thru the floor-construction. Therefore the base and the studding *both* move downward in response to the settling floor. In other words, the settlement is here *general* rather than *local*. Hence, no gap occurs between the finish floor and base. On the other hand, if the settlement continues, the base might buckle, or become split, because of the relative upward thrust of the excessively sagging floor. Moreover, this general settlement, not being equalized, is bound to open up a crack in the plastering at the junction of the ceiling and wall underneath. And, finally, the wide ribbon supporting the outer ends of the second floor joists is liable to more relative shrinkage than the plastering that covers it. This is the cause of numerous

Western Framing Which Strives to Eliminate All Unequal Shrinkage Settlement.

SKETCH · 4 ·

plaster cracks in this vicinity and, if this shrinkage is excessive, the plaster will buckle and, perhaps, fall from this portion of the wall.

Sketch No. 2 shows a cross-section of a "drop-girt" frame as called for by the most approved practice. At "A" is shown the original condition of the frame upon completion, while at "B" is shown the same construction after the usual shrinkage-settlement has taken place. While this frame is far superior, in every way, to the "balloon" frame, yet it is, nevertheless, subject to the same resultant evils, even tho these evils be of lesser extent. In the "drop-girt" frame, the second-story exterior studding and the outer ends of the second floor joists are supported upon the 4-inch by 8-inch girt, while the upper interior partition studding rests upon the 2-inch partition cap of the story below, as clearly indicated in the sketch. Moreover, the 6-inch by 14-inch first-floor girder is framed with the top of the joists. Consequently the *general* settlement has been almost, but not entirely, equalized. There will still be a slight sag in the floors and ceilings, but probably not enough to crack the plastering. The sag in the first floor, in this instance, is equal to the difference in settlement between the 14-inch girder and the 10-inch joists, amounting to but $1/24$ th of 4 inches, or a little more than an eighth of an inch, while the sag in the second floor will be not quite one-quarter of an inch, and the sag in the second-story ceiling will equal the difference in the total general settlement of the exterior and interior walls, amounting to exactly an eighth of an inch. But, as before said, this slight sagging will probably cause no serious damage. However, the *local* settlement occurring at the outer ends of the first floor joists, and at *both* ends of the second floor joists, cannot be so easily overlooked. At all of these points, as shown in the sketch, the vertical studding extends into the "zone" of the floor-construction. Hence, the floor settles in relation to the studding and therefore opens up a gap between the floor and base, being more pronounced at the second floor-level because of the greater depth of shrinkable material existing there between the top of the sub-floor and the bearing-surface of the joists. A gap of $1/2$ inch or more is not an uncommon occurrence. An attempt to remedy this fault is sometimes made by placing a base-shoe at the junction of base and floor, and nailing same to the floor only, thus keeping the gap "covered."

By groups of four squares as a unit separated by wider joints, the scale is increased.

A diagonal pattern of square tiles is emphasized by a border.

By a few rows of broken joints, an effect of border is produced in a field of square tiles.

When the small squares are less than one-quarter of the area of the large squares, the pattern runs off at the side.

When the small squares are one quarter of the area of the large squares, the pattern has more repose.

Another way to increase the scale with small tiles.

A decorative pattern that can be made on the job.

By breaking joints in one course, the border is made wide.

An arrangement adapted to large rooms.

When double squares are laid "basket pattern," the necessary allowance for joints adds interest.

A good pattern for corridors.

The simplest floor of square tiles is interesting if the joints are in scale.

When square tiles are laid with broken joints, long lines in one direction are the result.

Varieties of "herringbone."

Two combinations suggesting plaids.

A simple device for a panel or a floor for a large room.

Built-in Furniture--Some Interesting Designs

ONE of the charms of the interior of any home is the furniture which is built into it. The dressers, seats, bookcases more than half solve the problem of furnishing it.

Furniture that is built to fit the place it is in, is far more decorative and more comfortable than detached pieces could be in the same place. Not only is space saved by this means, but a keynote is given for the rest of the fittings in the home, which, unless it is utterly disregarded, will tend to keep the furnishings of the room in harmony.

Arrangement for Accordion or Four Fold Doors Showing Only Proper Way.

Accordion Folding Doors

THERE is nothing in the building line which puzzles the millmen, the carpenter, and the hardware man so much as accordion folding partitions.

The manufacturers of accordion hangers should treat more fully on this subject. They should place in the hands of the architects full descriptive matter, also half size or full size drawings with hardware in place. Then the architects can show the carpenter how it is done and also show the hardware man what items he has to furnish to make a perfect workmanlike job.

Doors should never be made thinner than $1\frac{3}{4}$ inches, because a lock knob and flush cup handle cannot be applied in doors thinner than $1\frac{3}{4}$ inches.

The detail below shows six full width doors and two half width doors.

Here you have a sliding door proposition because the hanging of the doors forces you to it. You must supply a hanger for the door farthest from the half door, and a hanger for every second door from this.

You can readily see that the track is full width of the

opening. You must use a sliding door lock with the regular flush cup escutcheons. You should use four flush extension bolts at the bottom. You cannot use flush bolts at the top because you cannot apply the strikes or keepers to the top jamb; *there is a slot in the top jamb.*

You can omit the use of the bottom bolts, but it is not good practice, because the doors will buckle and you have no other method of keeping the doors rigid at the bottom when same are closed.

If you wish to use eight full width doors and two half width doors you must use the same number of hangers as shown in the detail, but these two extra inner doors must be treated to operate same as regular pair of hinged doors with a soffit closing up the slot in the top jamb and bolts, lock, knob and flush cup handle.

Now, to obtain a good workmanlike job of folding partition doors, the writer suggests the use of the adjustable hanging strip as shown in detail to left.

If the doors shrink the flush bolts can be shot into their keepers. All makers of hardware furnish keepers or strikes with oblong holes in them (because they know doors will shrink), hence the strikes or keepers need not be moved.

Plan View of Tracks for Four-Door School House Partition Heavy Enough to Carry Blackboard Panels; with Detail View of Pocket for Doors to Slide Back Into.

School-Room Partition Doors

ARRANGEMENT OF PARTITION DOORS HEAVY ENOUGH TO CARRY BLACKBOARD PANEL

WE show herewith, in the bottom detail, four sliding doors, all of which slide back into one pocket.

You will notice that this scheme is to take the place of accordion folding doors, dividing a large room into two or more smaller rooms.

This is especially desirable if these partition doors are required for additional blackboard space.

This device is in common use in the Chicago public

schools, and is being installed in many of the schools in the larger cities. The accordion folding doors are much lower in price; but price does not count when a perfect up-to-date device is wanted.

Any number of doors can be used. If you have the space for a pocket in the opposite wall you can slide some of the doors into same.

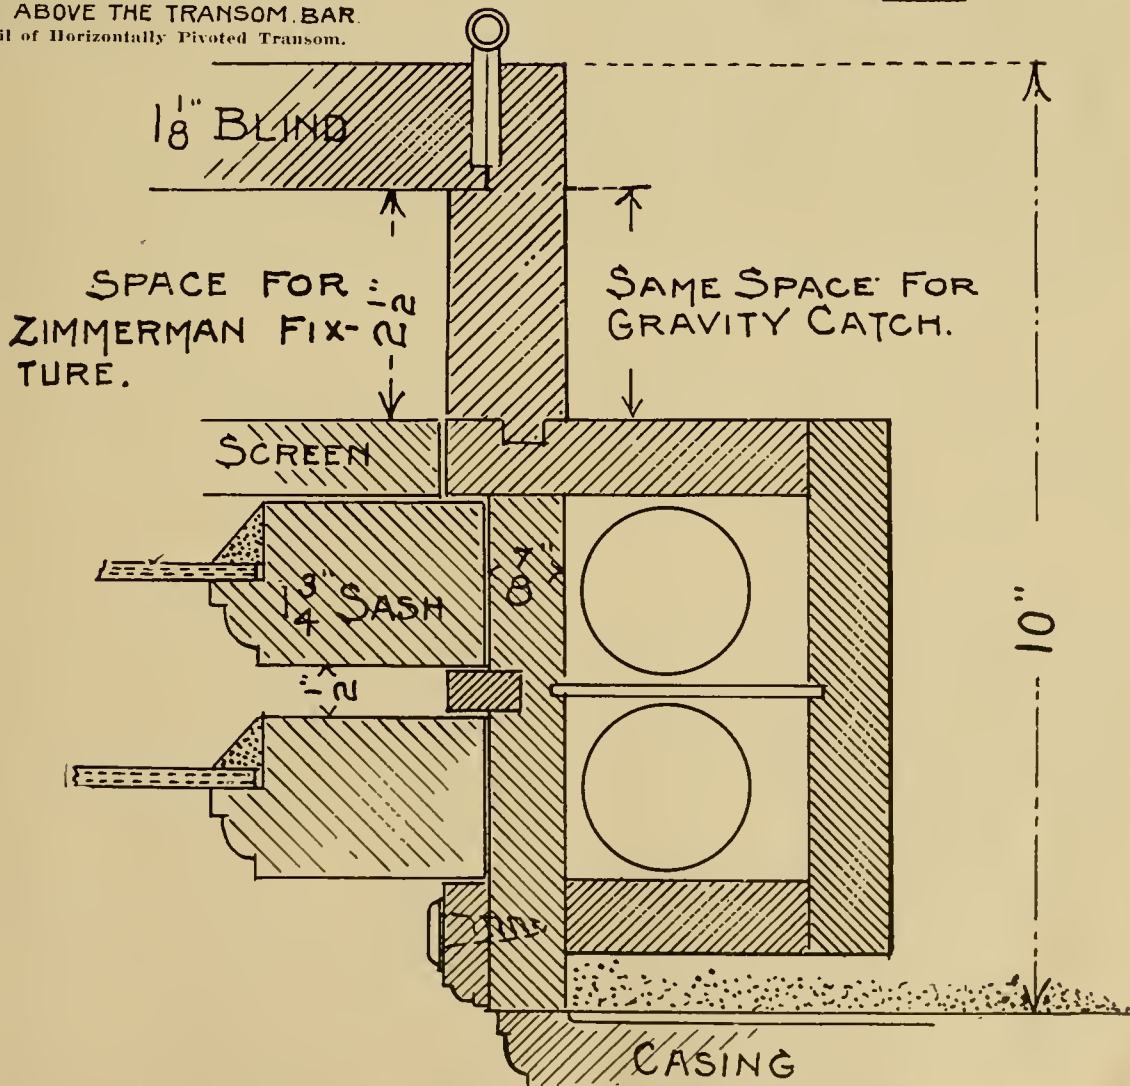

If it is desired to hide these doors, a panel can be placed in front of the doors when same are back into the pocket.

This panel can be hung on invisible hinges and a very satisfactory job is obtained.

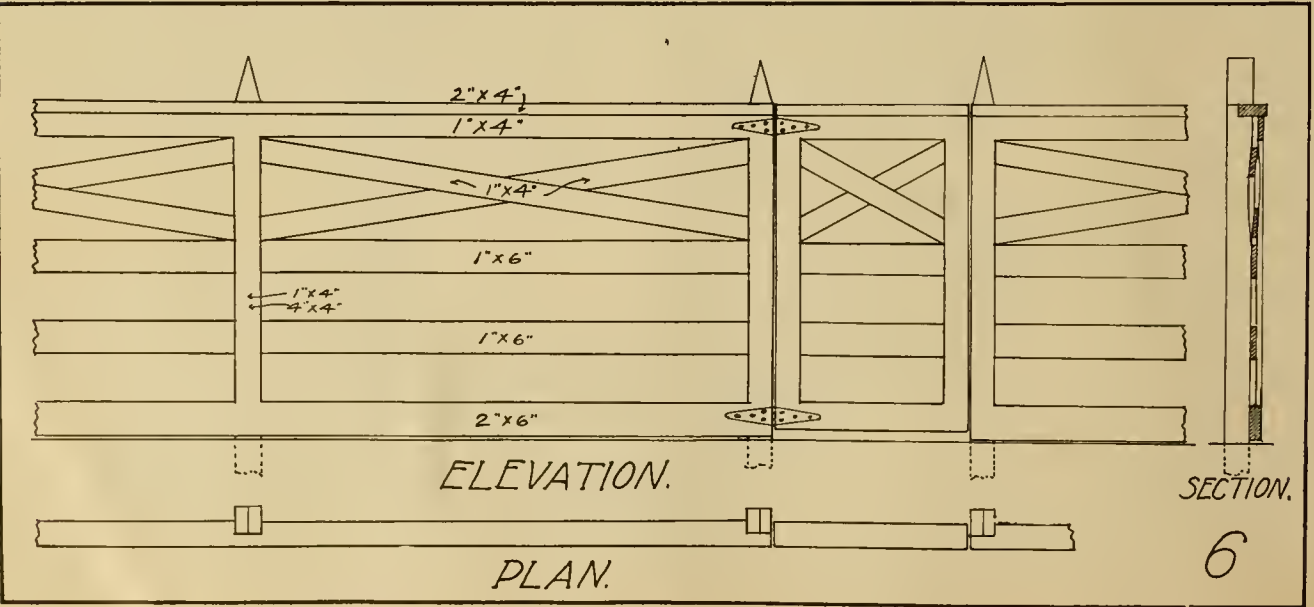

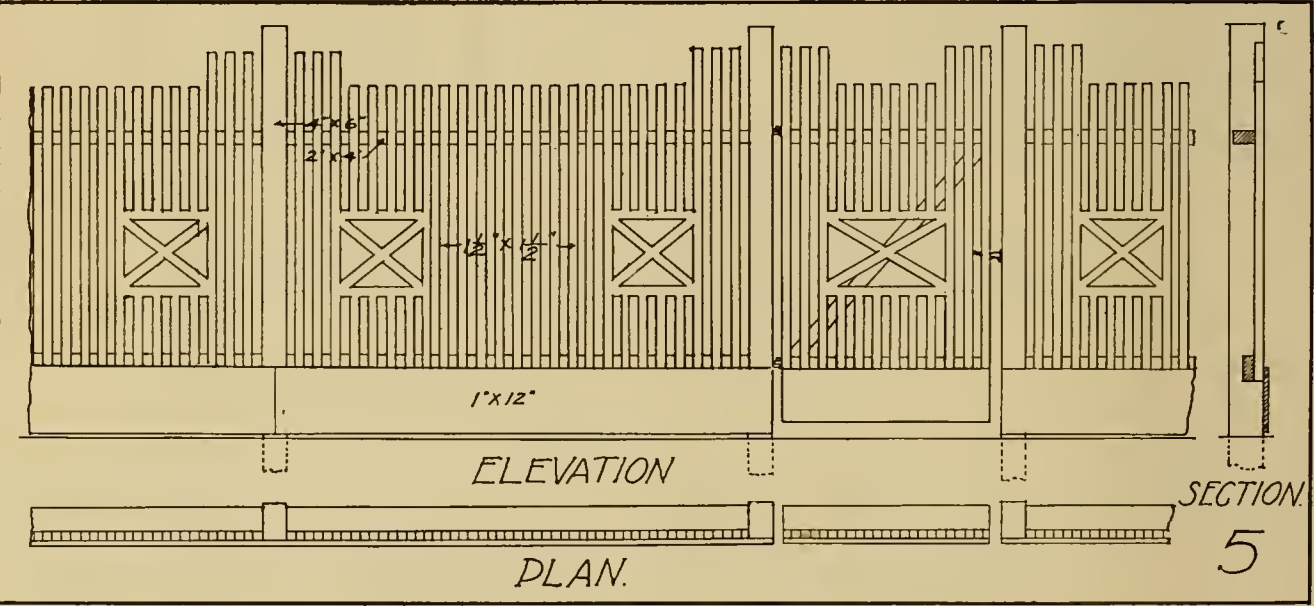

DOOR JAMB.

Sun Parlor and Sleeping Porch Modernize Old Homes

THERE are few houses that were built before sun parlors and sleeping porches came into demand that cannot be remodeled so as to have these modern features. The cost of the additional rooms is more than gained by the satisfaction they give the owner and the increase in the value of the house, should it be sold.

In designing a sun parlor, or a sun parlor and sleeping porch, first consider the type of architecture of the house and place the addition where it will most improve the dwelling. The addition here shown was placed at the side of the house, at the front. This is constructed of face brick, set on a concrete foundation, with a stucco strip below the sleeping porch windows. Details of the construction are given in the section.

The floor plan of the sun parlor, or living porch, calls for a tile floor, but any material suitable or wanted by the owner can be substituted. The glazed doors leading from the living room to the porch also can be changed into any other desirable type, or left out altogether.

In this design the roof line was extended out over the porch to conform to that of the rest of the building. That is a feature that should not be overlooked—to so design and build the addition that it will not appear as an addition, but apparently will be a part of the original construction.

As has been said, this design is susceptible to many alterations. For instance, the living porch here shown can be transformed into an outdoor dining porch, adjoining the dining room, with a sleeping porch above. When such an addition is made, the construction will be more simple, as dining porches usually were merely screened in, being placed in a position where there is more privacy.

COMMUNITY HOG HOUSE WITH CONCRETE YARDS.

Bank Building and Lodge Hall

SINCE the building which is to contain a banking business and lodge hall is sure to become the center of business and social activities among the men in the community in which it is erected such a building should be somewhat out of the class of commonplace structures. Good substantial construction to which is added the necessary artistic treatment required to place it in somewhat of a class by itself are the most important of the several factors to be considered in the design of such a building. The finish of the exterior may be made very impressive by the use of ornamental face brick with terra cotta trim. The use of these materials has come to be standard in city construction and there is nothing which impresses the stranger with the progressiveness of a town more than to see the business section being built up with structures in which these modern materials are used.

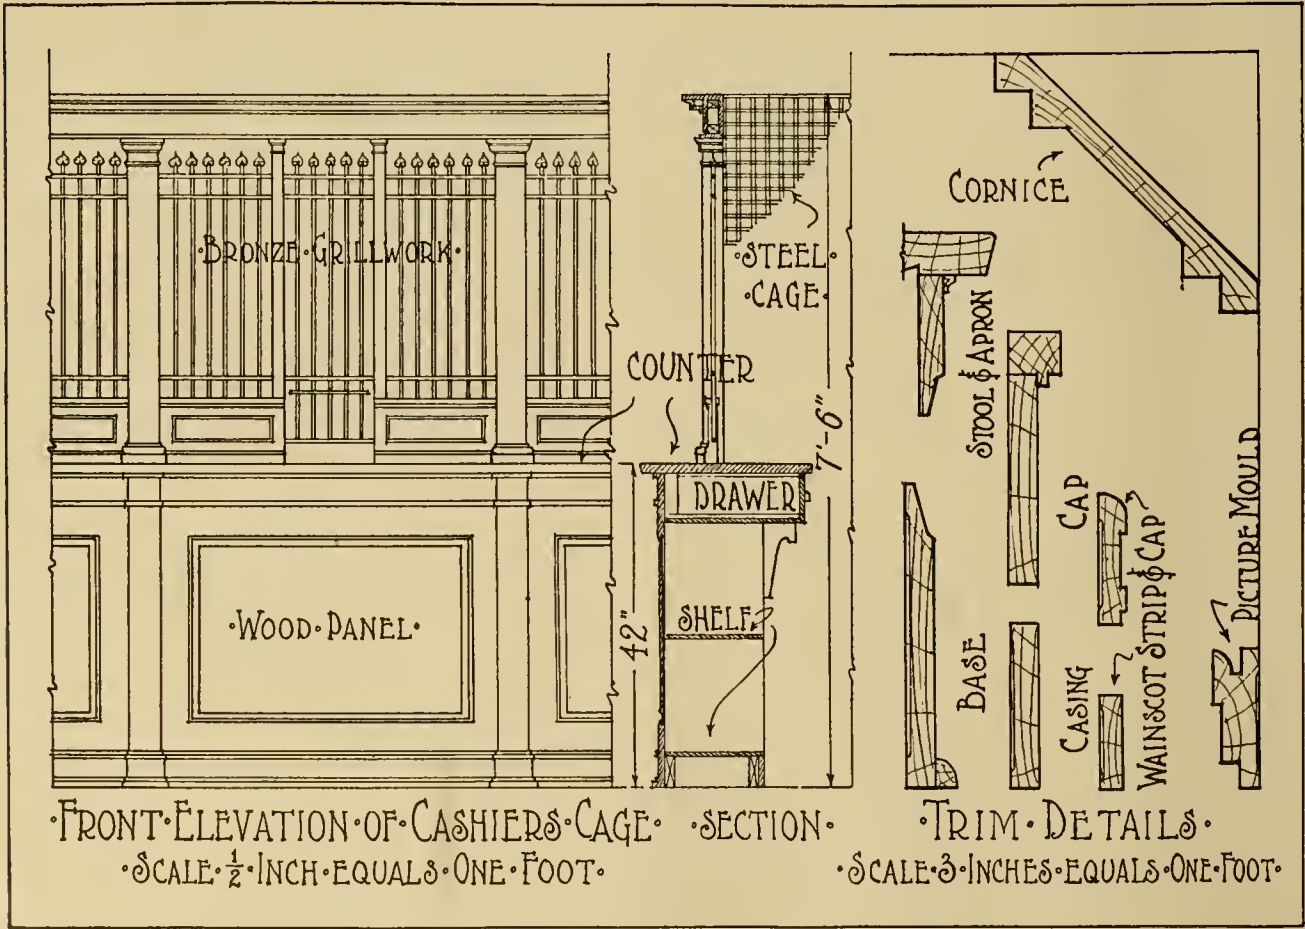

The building illustrated here occupies a corner lot and is 30 by 50 feet. The entire first floor is designed as a bank and the second floor is taken up by the lodge hall. The ornamental front is placed on the 30-foot side of the building. The portions of the front wall above the first floor windows and between the sets of second floor windows are finished with face brick while the entrance, columns and entablature are built of terra cotta. The small-paned windows add a great deal to the distinctive appearance of the building. There is a sufficiently elaborate treatment given all of the details to mark this building as one of importance among the various structures along the street upon which it would be placed.

The heavy brass trimmed door of the bank opens into a small vestibule in which there are entrance and exit doors connecting with the main corridor. At the right upon enter-

First Floor Plan. Second Floor Plan.
Arrangement of Bank Building.

ing is a private office having doors both into the public square and into the banking space. Three cages are placed facing the side wall of the building and bounding the main corridor near the front of the bank. These cages are built up of wood panels from the floor to the counter, which extends from the private office along the side of the first cage and along the front of the three cages down the corridor. Above the counter there is a bronze grillwork on the outside of the cages and steel lattice partitions are used between cages.

Roof Truss for 36-Foot Barn

Question—Would plank frame construction be heavy enough for a barn 36 feet wide, or would it be advisable to use another form of truss? What size plank should be used in a barn 36 feet wide, using 18-foot studding, 2 by 6's? There will be 2 by 6 rafters, two 2 by 6's for plates, 4 by 6's for sills, 2 by 10's for joists, and two 2 by 12's for girders, with 4 by 6 supports placed 9 feet apart. The joists would be 16 feet long between wall and girder.

Would you advise tying with a 2 by 6 at a point just below the plate to the floor joists, say at an angle of 45 deg.? The braces on the rafters are to be 1 by 8's.

Answer—If you will cover the joints of the intersecting rafters with 1 by 8-inch cleats on each side, it will strengthen

this point very much (see detail at section A-A). The 1 by 8-inch braces on each side of the rafters are heavy enough for a barn of ordinary construction, if it is not exposed too much to high wind.

For a barn with 18-foot studding use 2 by 6-inch timbers instead of 1 by 8-inch for the lower brace.

If the barn is exposed to high winds, we would advise tying with a 2 by 6-inch at the point just below the floor joists, spaced 8 feet on centers.

In regard to the floor joists, 2 by 10-inch are not heavy enough for a span of 16 feet with the amount of hay storage that you have to carry. We would recommend using 2 by 12-inch joists and spacing the posts 11 feet 6 inches from the outside wall. This would make the span more evenly spaced.

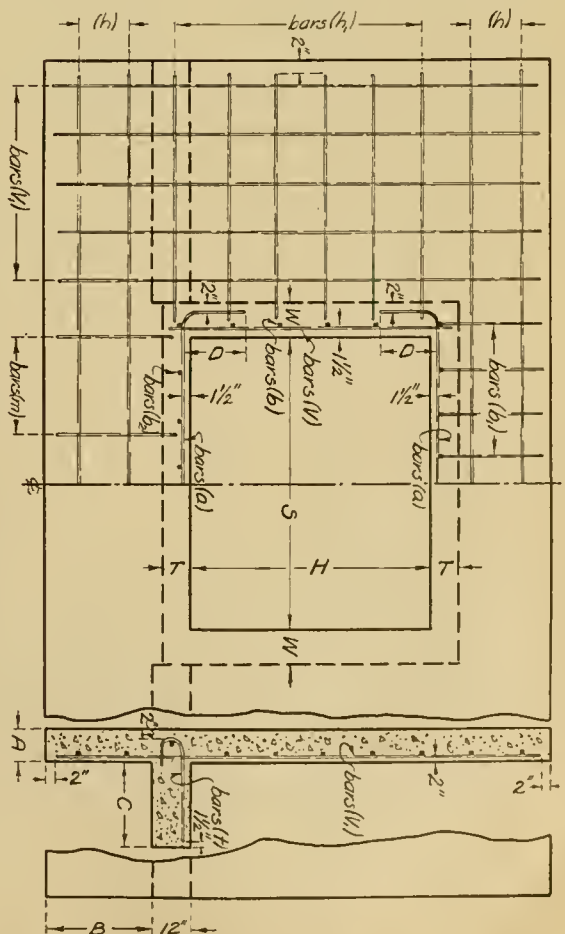

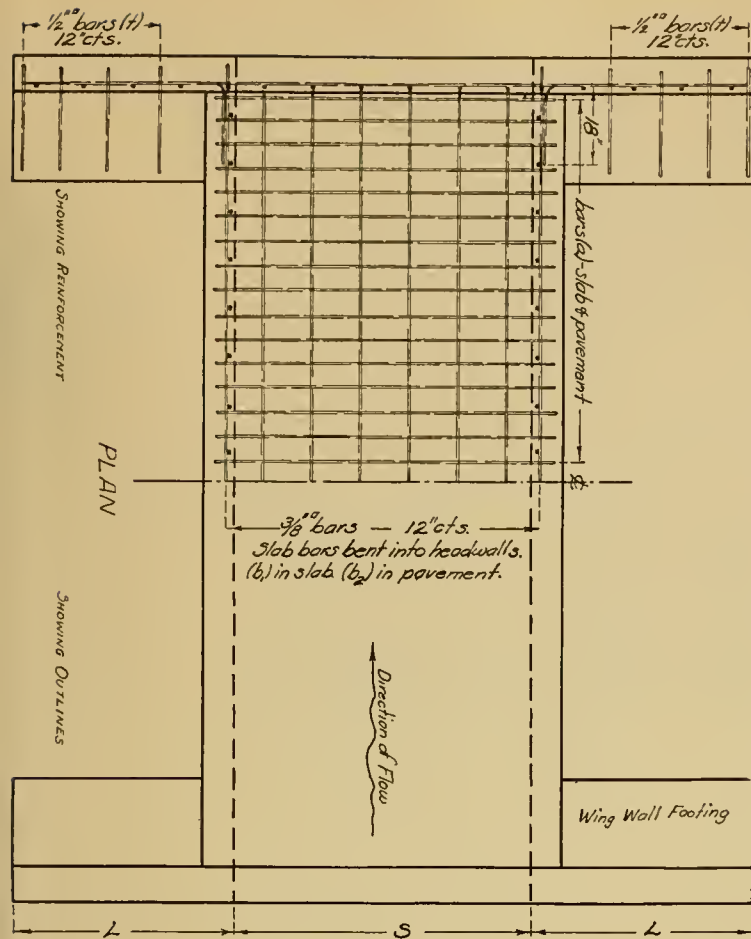

Detail Showing Recommended Sizes for Various Members in Plank Frame Barn That Is 36 Feet Wide.

Note—Culverts having spans of 4-0 or less may be constructed with out-eungored footings if the bars are placed 12" from outer face of side walls and bent 18" into headwall, 1½" from outer face. (If bars are also moved to outer face of side walls, Distance B should be 12" on up-stream, and 2'-6" on down-stream end, measured from bottom of pavement with footing omitted.) In culverts of span 4'-0" or under, 2-(b) bars are placed 4" from top of headwall, 2" from either face and (b) bars are bent into center of wall.

All steel should be mild or medium first grade stock. Lengths not indicated should be figured with the end clearances shown in the diagram and should be obtained in the full lengths indicated or calculated.

Bevel all exposed edges with 3/4" triangular mounding.

Length A as calculated from the equation given below implies a slope of 1½ to 1 for earth fill falling around ends of headwalls.

Dimensions shown are not intended to apply to culverts carrying heavy fills. Culverts of span 4'-0" or under will carry fill of 4'-0" only; all others are designed to carry fill of 1'-0" only.

Concrete should be proportioned 1-2½-4 thruout.

DESIGN AND CONSTRUCTION OF SPECIAL HIGHWAY DRAINAGE STRUCTURES.
Plan for Reinforced Concrete Box Culverts of Span 12 Feet or Less and Height 9 Feet or Less.

General Elevation

Letter	No.	Size	Length
V	36	3 ¹ / ₂ "	5'-0"

C ₂	15	"	22'-6"
C ₃	86	"	7'-0"
b ₁	25	3 ¹ / ₂ "	23'-0"
b	33	"	19'-0"
t	24	2 ¹ / ₂ "	3'-9"
m	13	"	4'-0"
Steel	5735*		

To be constructed in accordance with the State of Illinois State Highway Dept. Contract Form and General Specifications for Bridge Work. Edition of July, 1915.

All exposed edges to be beveled with $\frac{3}{4}$ triangular molding.

Where grooved panels are shown the same to be made with 1 $\frac{1}{2}$ triangular molding.

Place 3" tie drains in side walls about 18" above pavement. Grt. Crk.

Class A concrete to be used throughout.

Proportions 1 - 2 $\frac{1}{2}$ - 4.

All steel reinforcing bars must be mild or medium steel rolled from new billets.

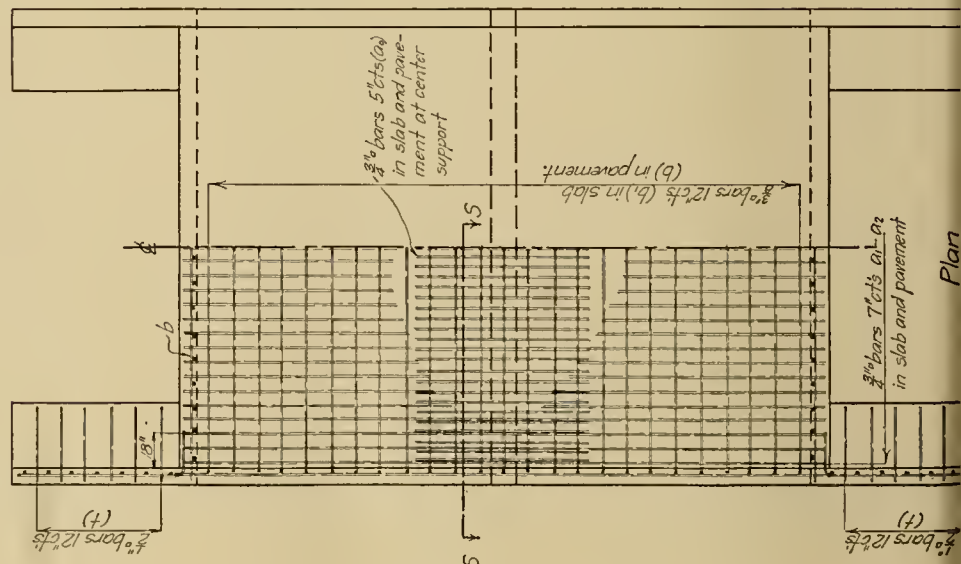

No rolled material or light carbon steel will be permitted.

All bars must be obtained in the full lengths indicated in bill of material.

Grt. - two girts in corner post & side of road. S side of road.

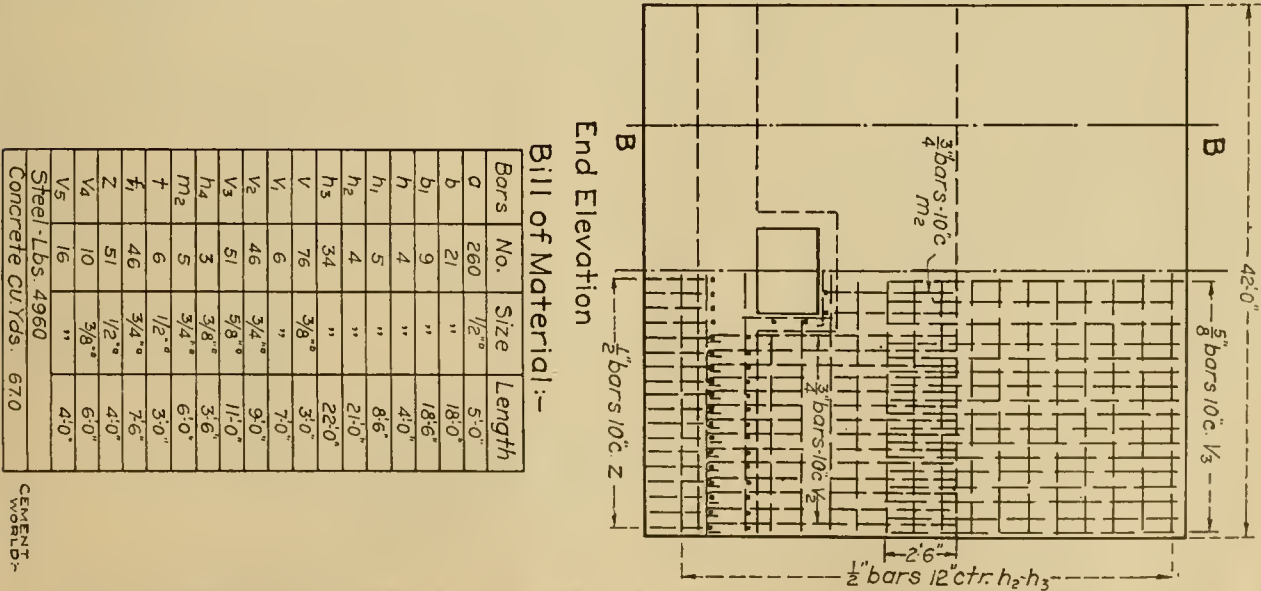

End of Wing

Plan

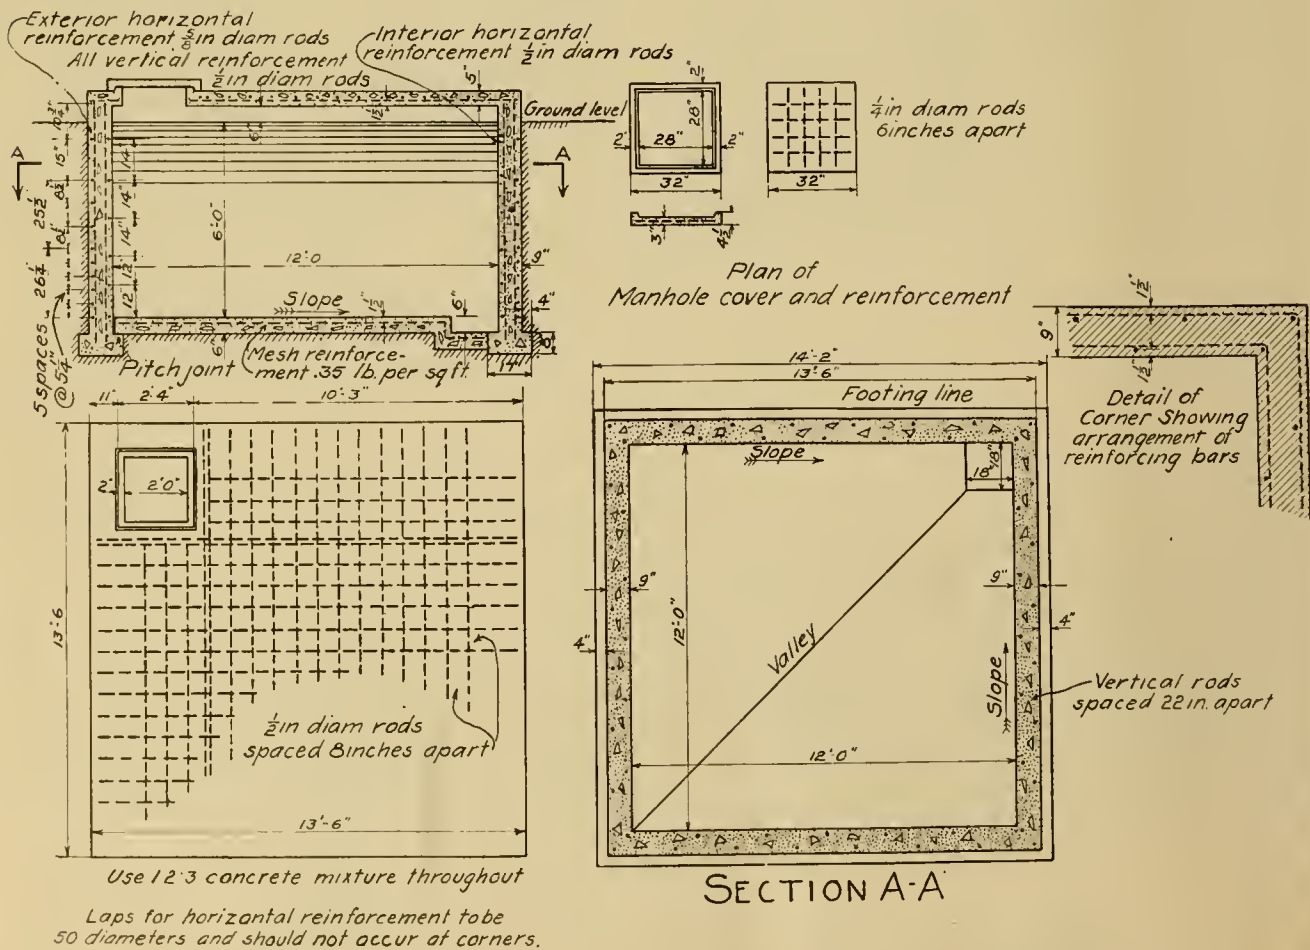

Plans
of
Brandt Bridge
Roscoe, Twp.,
1916

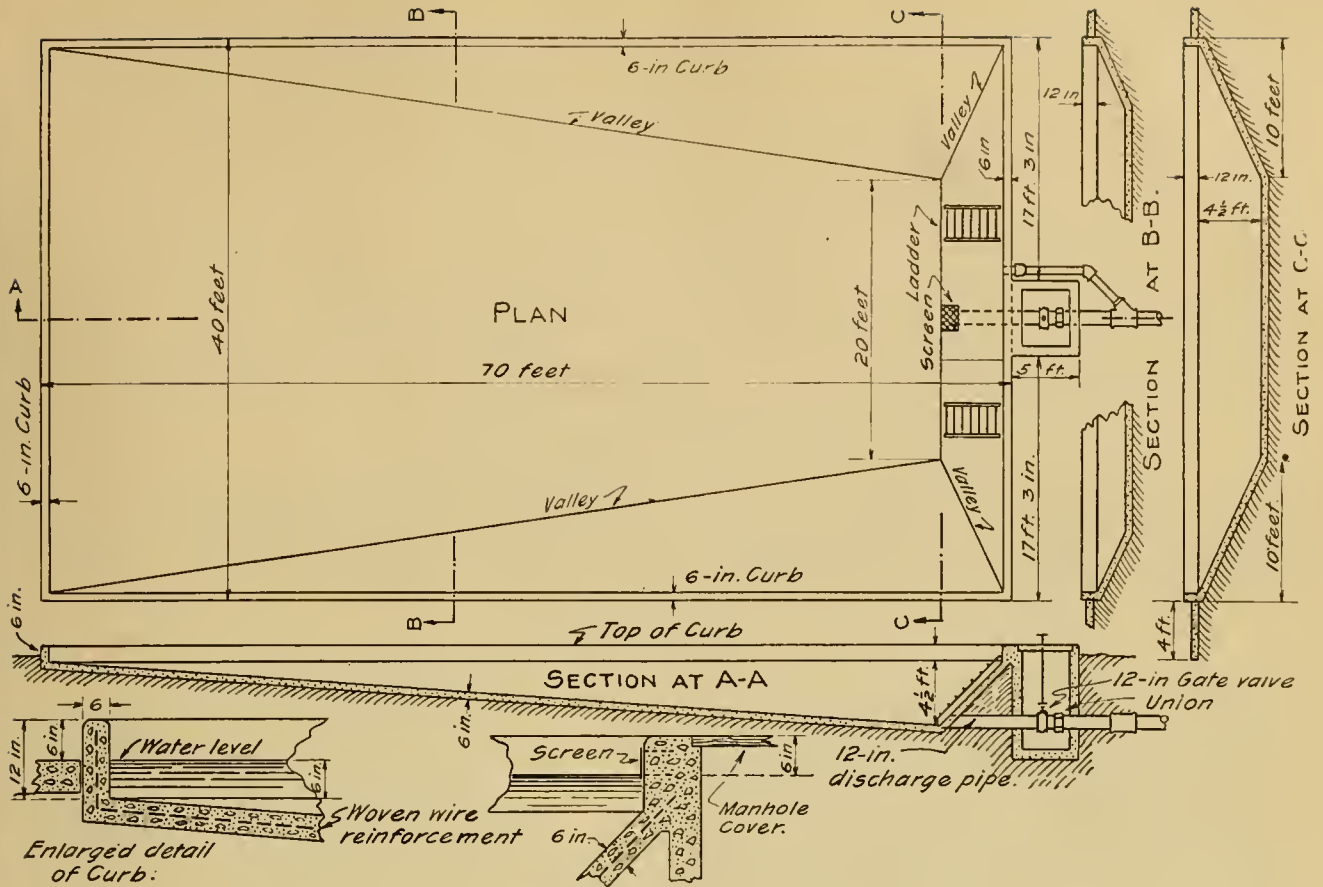

DESIGN AND CONSTRUCTION OF SPECIAL HIGHWAY DRAINAGE STRUCTURES. Reinforced Concrete Culvert to Bring Water Down to a Lower Level. Conditions Requiring This Type of Culvert Are Common in McDonough County, Illinois, Where This Design Was Developed in State Aid Highway Drainage Work.

Storage Cellar with a Capacity of 800 Bushels. Greater or Less Capacity Can Be Secured by Adding to or Taking from the Length of the Plan, Each Additional Foot of Length Increasing the Storage Capacity 40 Bushels.

Construction Details of a Reinforced Concrete Tank Designed to Hold 6,000 Gallons of Oil.

Details of Concrete Swimming Pool.

Plans for a Concrete Dipping Vat for Cattle, as Recommended by the U. S. Department of Agriculture.

LIBRARY OR STUDY TABLE.

STOCK BILL FOR LIBRARY TABLE

Top, 1 piece, 1 by 30 1/2 by 45 1/2 inches, S-2-S.
 Legs, 4 pieces 2 1/2 by 2 1/2 by 29 1/2 inches, S-4-S.
 Back rail, 1 piece, 3/4 by 5 1/4 by 37 inches, S-2-S.
 End rails, 2 pieces, 3/4 by 5 1/4 by 26 inches, S-2-S.
 Front rail, 1 piece, 3/4 by 2 by 37 inches, S-2-S.
 Shelf, 1 piece, 3/4 by 11 1/4 by 40 inches, S-2-S.
 Drawer facings, 2 pieces, 3/4 by 3 1/4 by 16 inches, S-2-S.

Drawer sides, 4 pieces, 3/8 by 3 1/4 by 26 inches, S-2-S.
 Drawer backs, 4 pieces, 3/8 by 3 by 16 inches, S-2-S.
 Drawer bottoms, 2 pieces, 3/8 by 26 by 16 inches, S-2-S.
 Drawer slides, 3 pieces, 3/4 by 2 3/4 by 26 inches, S-2-S.
 Drawer guides, 3 pieces, 3/4 by 1 1/2 by 26 inches, S-2-S.
 Tie, over drawers, 1 piece, 1/2 by 2 3/4 by 36 inches, S-2-S.

The remaining pieces, keys, and short facings about the drawers may be got from scrap stock.

Construction Details of a Strong and Serviceable Piano Bench.

STOCK BILL FOR PIANO BENCH, GIVING FINISHED SIZES

Cover, 1 piece, 7/8 by 15 1/2 by 40.
 Posts, 4 pieces, 1 3/4 by 1 3/4 by 18 3/4 (one 1-inch tenon).
 Frame, 2 pieces, 3/4 by 4 by 37 3/4.
 2 pieces, 3/4 by 4 by 13 1/2.
 Lower rail, 2 pieces, 1 3/4 by 1 3/4 by 13 1/2.

Stretcher, 1 piece, 3/4 by 4 by 35 1/8 (two 7/8-inch tenons)
 Blocks, 4 pieces, 5/8 by 1 1/2 by 1 1/2.
 Bottom, 1 piece, 5/16 by 12 by 36 1/4 (wallboard).
 2 pieces, 3/8 by 3/8 by 33 3/8.
 2 pieces, 3/8 by 3/8 by 9 1/2.
 Hardware, 1 pair 3/4 by 2 1/2 nickel plated butts.
 16 1 1/2-inch No. 10 F. H. screws.
